1) Deploy a trained ML model locally such that it can accept user input and return predictions. Clearly define each step involved in this deployment

2) Run multiple ML experiments while logging parameters, metrics, and trained models using MLflow

3) Train a simple machine learning model and save it to disk using an joblib/pickel

4) Clean a dataset by handling missing values and apply normalization and standardization techniques on numerical features using pyspark in databricks notebook

5) Prepare a dataset for machine learning by encoding categorical variables using pyspark in databricks notebook

6) Perform aggregations on data using grouping operations and combine multiple datasets using appropriate join strategies(pyspark in databricks notebook)

7) Initialize a Git repository for a local project and verify its status before and after initialization

8) Track changes in project files by staging and committing them with meaningful commit messages

9) Create and manage multiple branches for feature development and Simulate a merge conflict and

resolve it manually

10) Create a multi agent project with txt doc as input, llm processing and response in csv file for download
